

# TechGI IV - ComDiS

## ComDis

Introduction to  
**C**ommunication Networks  
and **D**istributed Systems

*DHTs, Naming Summary*

# Reminder:

- **We have discussed the mapping**

*Name* → *Address*

- **The solution has been DNS**

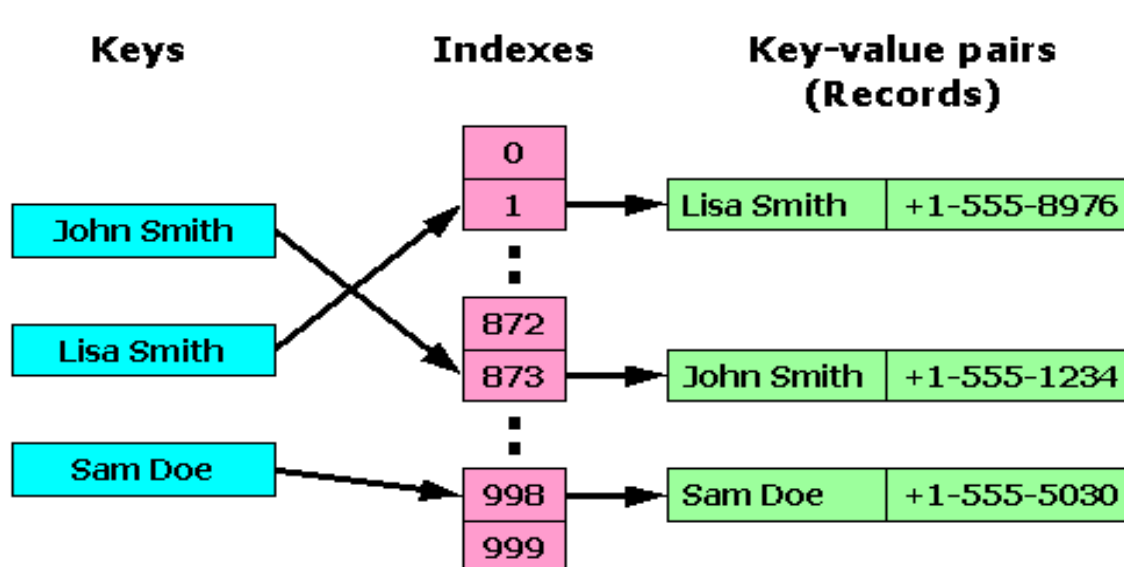

- Hierarchical organization
- Distributed
- Using redundancy

- **Challenge:**

**How to provide storage of pairs - like the above one – in a distributed way, even if there is no strong hierarchy?**

# Hash Tables (a classic)

- Items: [Key, Value] are stored
- The key is *hashed*, i.e. transformed (using a *hash function*) so that the result – **the hash** – can be used to locate a **bucket** in which the pair is stored. The bucket is identified by an **index**.

In this example the index is simply the number of the record.

- The bucket might contain multiple such items (pairs)!

# A Distributed Hash Table (DHT)

- Remember the mapping of NAMES to IP Addresses?  
Could we use Hash tables? Remember the scaling issue...
- Distributed Hash Tables spread the pairs across a number of computers (buckets) located arbitrarily across the world.

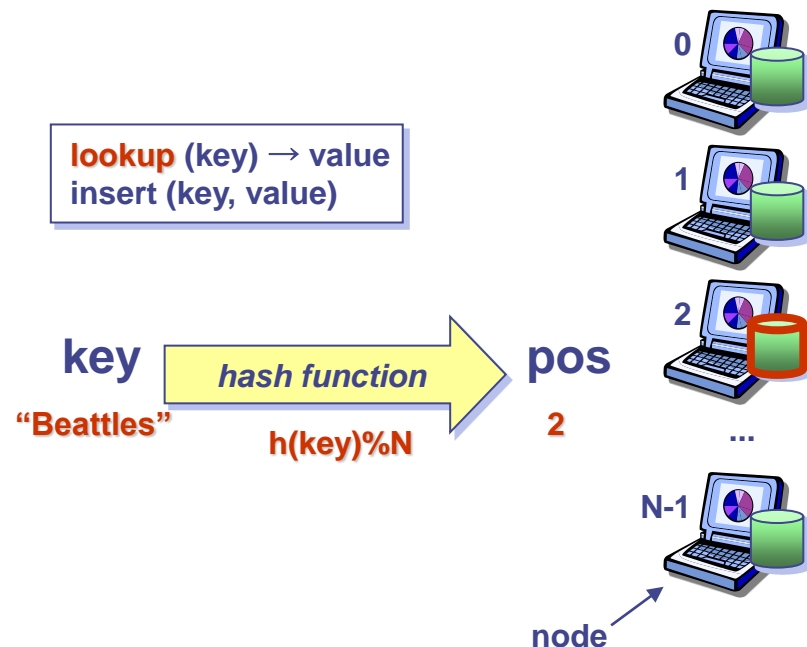

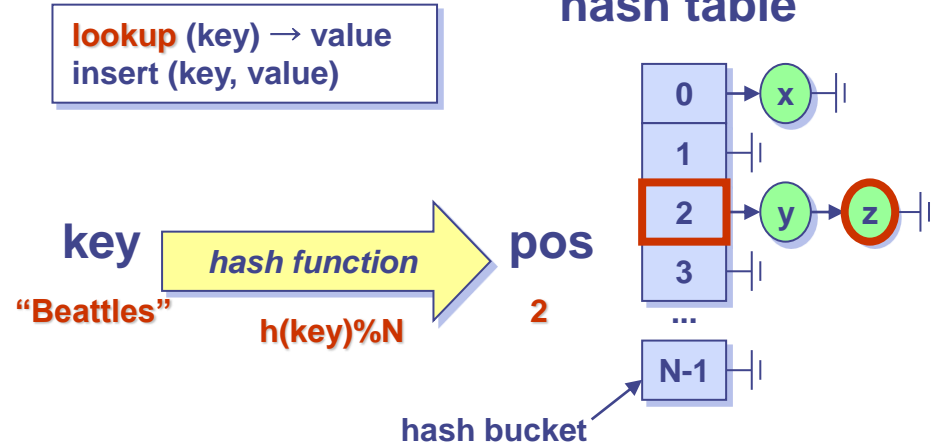

*Note: Copies of a single pair can be stored in one or in multiple locations!*

- When a user queries the system, i.e. provides the key, the system uses the hash to find the pair from one of the computers where it's stored and returns the result.
- All the nodes are assumed to be reachable by some kind of unicast communication.
- DHT possesses the features of :  
scaling, robustness, self-organization.

# The hash table vs. DHT

[Ala Khalifeh, UCI]

- The key is hashed to find the proper bucket in a hash table
- In a Distributed Hash Table (DHT), nodes are the hash buckets
  - Key is hashed to find the responsible Node
  - Pairs are distributed among the nodes with respect to load balancing

# DHT Interface

- Minimal interface (data-centric)

Lookup(key) → value

Insert(key, value)

Delete (key)

- Supports a wide range of applications, because few restrictions
  - Value is application dependent
  - Keys have no semantic meaning

**Note:** DHTs do *not* have to store data useful to end users, e.g. data files...

*Data storage can be build on top of DHTs*

- **Problem 1 (dynamicity):** adding or removing nodes
  - With hash mod  $N$ , virtually every key will change its location!  
$$h(k) \bmod m \neq h(k) \bmod (m+1) \neq h(k) \bmod (m-1)$$
- **Solution:** use consistent hashing
  - Define a fixed hash space
  - All hash values fall within that space and do not depend on the number of peers (hash bucket)
  - Each key goes to peer closest to its ID in hash space (according to some proximity metric)

---
- **Problem 2 (size):** all nodes must be known ( in order to insert or lookup items!)
  - Works with *small* and *static* server populations
- **Solution:** each peer knows of only a few “neighbors”
  - Messages are routed through neighbors via multiple hops

- The number of neighbors for each node should remain “reasonable” (**small degree**)
- DHT routing mechanisms should be decentralized (**no single point of failure or bottleneck**)
- Should **gracefully handle nodes joining and leaving**
  - Repartition the affected keys over existing nodes
  - Reorganize the neighbor sets
  - Bootstrap mechanisms to connect new nodes into the DHT
- DHT must provide **low stretch**
  - Minimize ratio of DHT routing vs. unicast latency between two nodes

# Identifier to Node Mapping Example [S.Shenker and I.Stoica, UCB]

- Associate to each node and item a unique *id* in an *uni*-dimensional space  $0.. (2^m-1)$

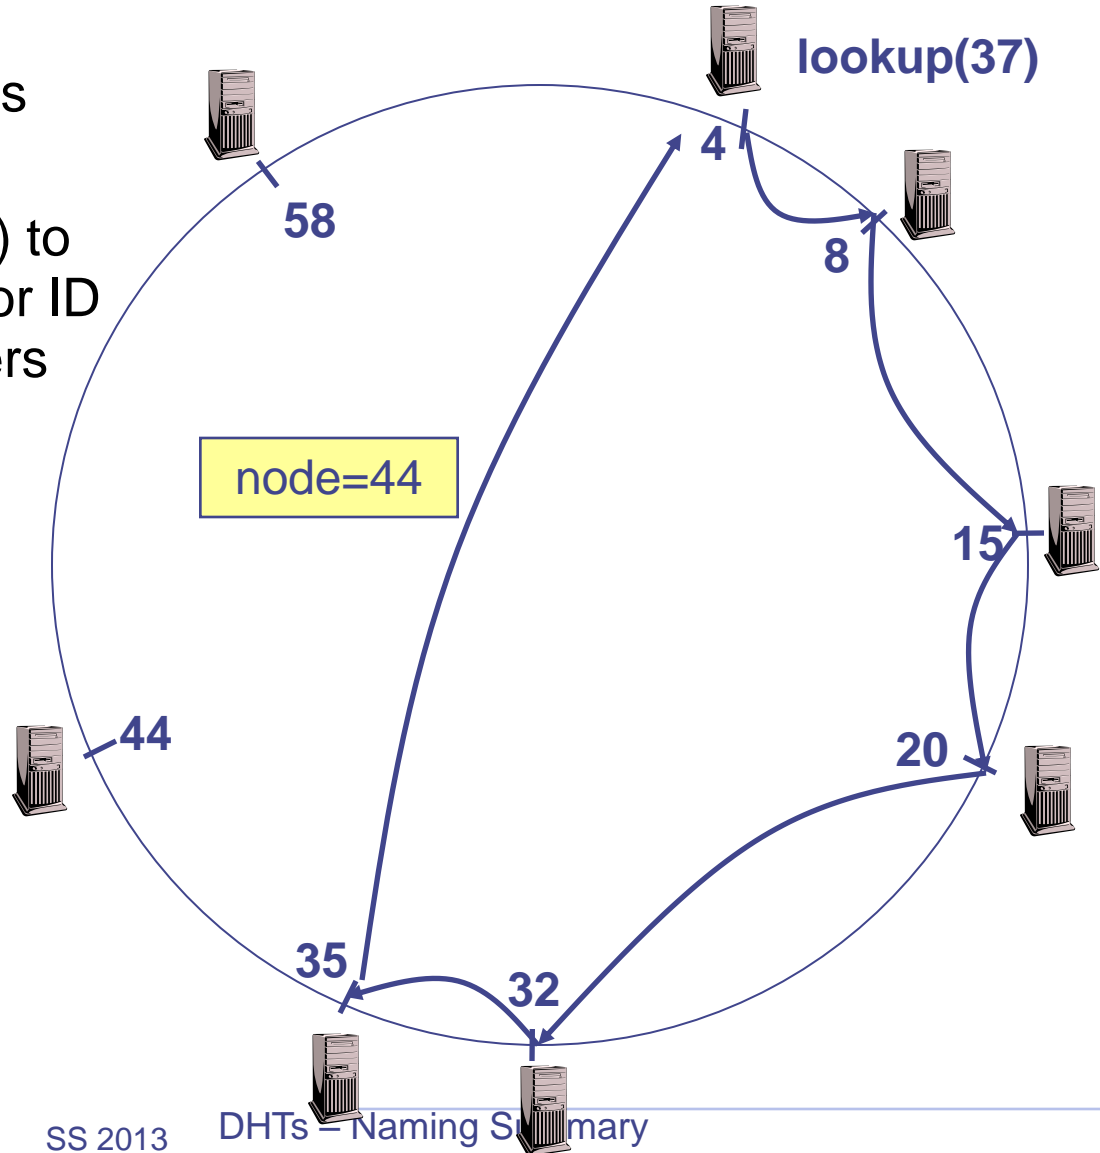

- Node 8 maps [5,8]
  - Node 15 maps [9,15]
  - Node 20 maps [16, 20]
  - ...
  - Node 4 maps [59, 4]
- 
- Each node maintains a pointer to its successor

# Chord Lookup

[Scott Shenker and Ion Stoica, UCB]

- Each node maintains its successor
- Route packet (ID, data) to the node responsible for ID using successor pointers

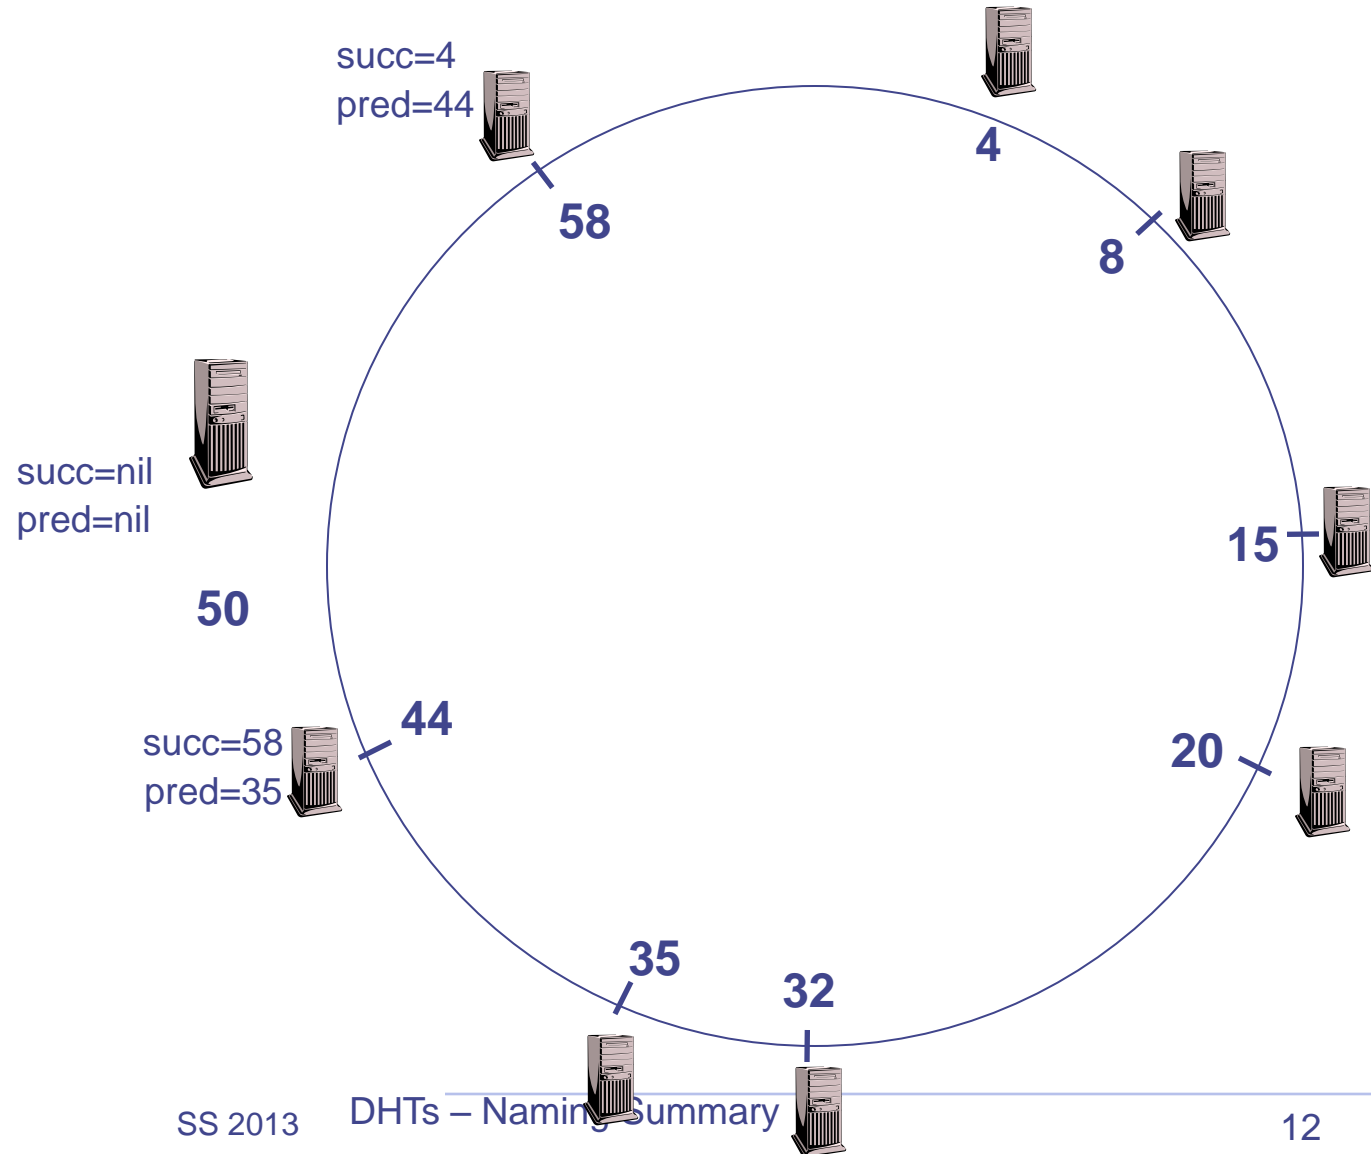

- Each node A periodically sends a **stabilize()** message to its successor B
- Upon receiving a **stabilize()** message node B
  - returns its predecessor  $B' = \text{pred}(B)$  to A by sending a **notify( $B'$ )** message
- Upon receiving **notify( $B'$ )** from B,
  - if  $B'$  is between A and B, **A updates its successor to  $B'$**
  - A doesn't do anything, otherwise

# Joining Operation

[Scott Shenker and Ion Stoica, UCB]

- Node with id=50 joins the ring
- Node 50 needs to know at least one node already in the system
  - Assume known node is 15

# Joining Operation

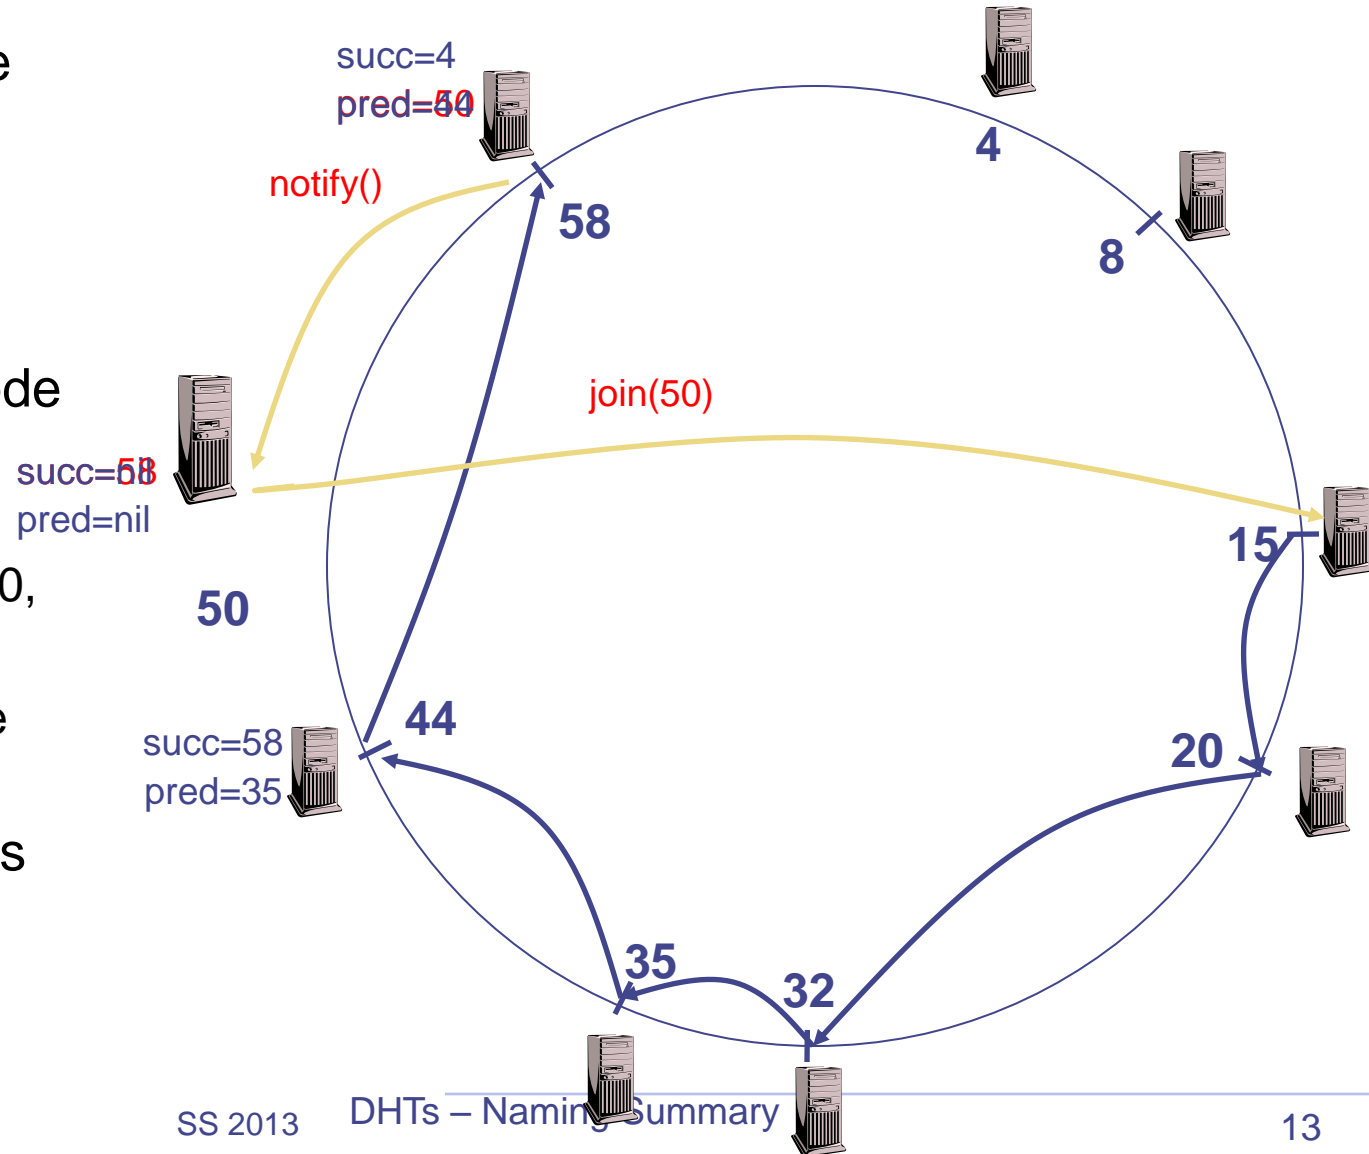

[Scott Shenker and Ion Stoica, UCB]

Node 50 asks node 15 to forward join message

When join(50) reaches the destination (i.e., node 58), node 58

- 1) updates its predecessor to 50,
- 2) returns a notify message to node 50

Node 50 updates its successor to 58

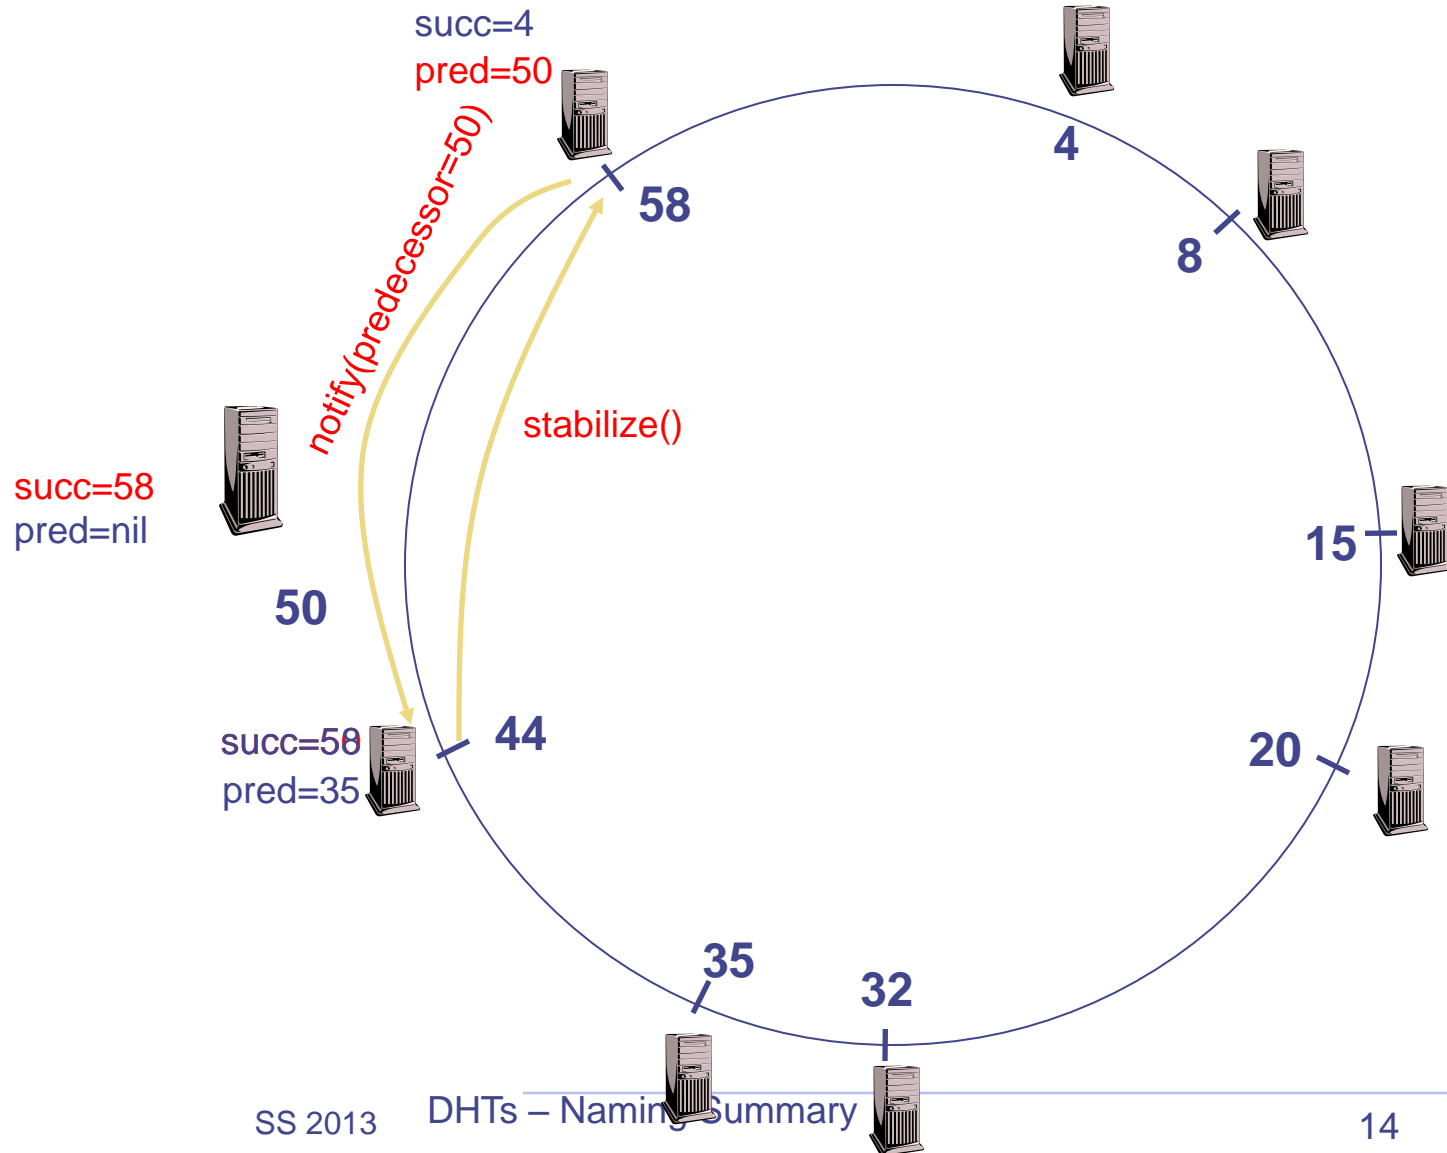

# Joining Operation (cont'd) [Scott Shenker and Ion Stoica, UCB]

Node 44 sends a stabilize message to its successor, node 58

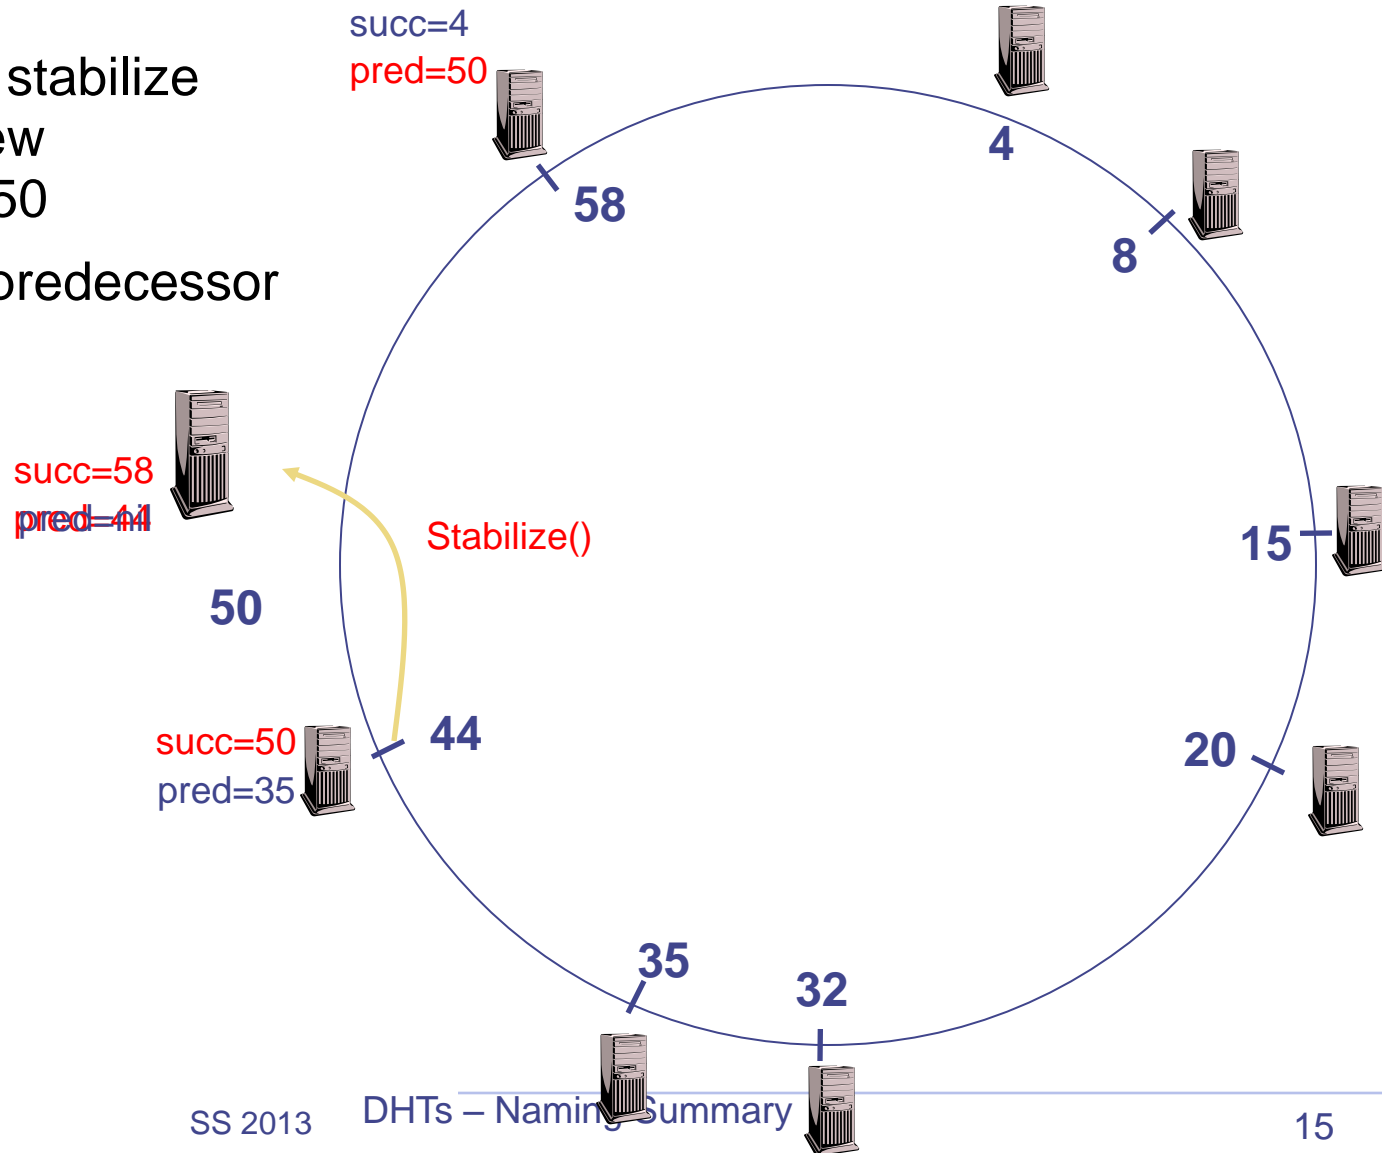

Node 58 reply with a notify message

Node 44 updates its successor to 50

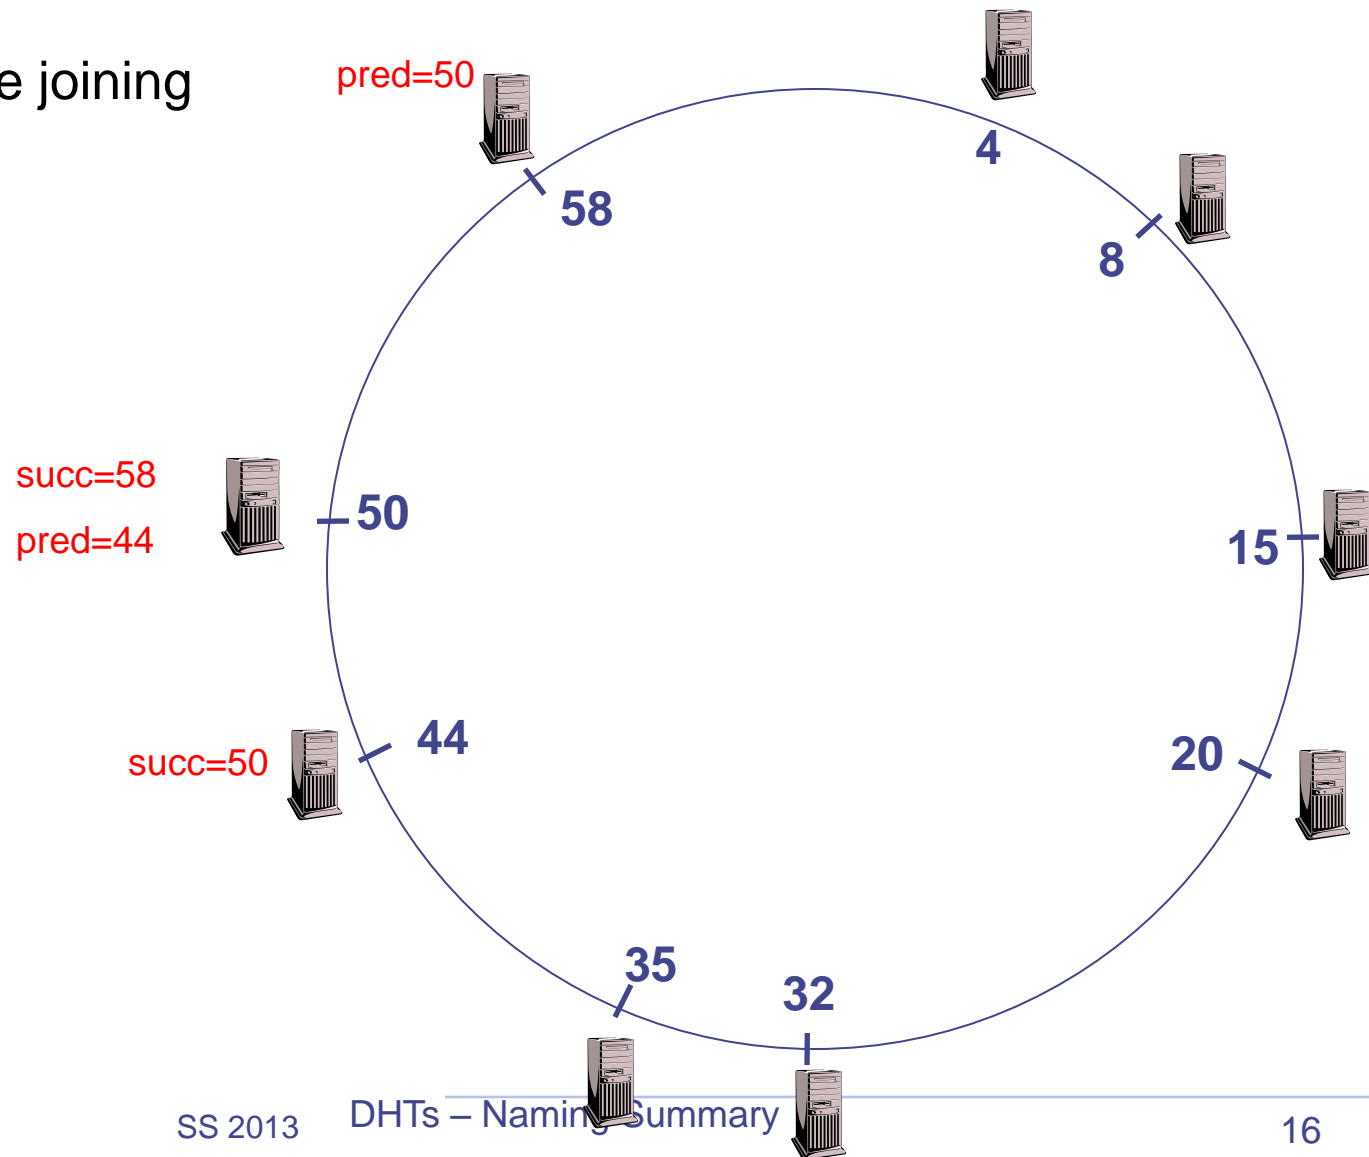

# Joining Operation (cont'd)

- Node 44 sends a stabilize message to its new successor, node 50
- Node 50 sets its predecessor to node 44

# Joining Operation (cont'd)

- This completes the joining operation!

# Achieving Efficiency: *finger tables*

Say  $m=7$

Finger Table at 80

| $i$ | $ft[i]$ |
|-----|---------|
| 0   | 96      |
| 1   | 96      |
| 2   | 96      |
| 3   | 96      |
| 4   | 96      |
| 5   | 112     |
| 6   | 20      |

$i$ th entry at peer with id  $n$  is first peer with id  $\geq n + 2^i \pmod{2^m}$

# Chord Performance (improvements)

- Chord Properties

- Routing table size  $O(\log(N))$  , where  $N$  is the total number of nodes
- Guarantees that a file is found in  $O(\log(N))$  steps

- Reducing latency

- Chose finger that reduces expected time to reach destination
- Chose the closest node from range  $[N+2^{i-1}, N+2^i)$  as successor

- Stretch is another parameter....

latency for each lookup on the overlay topology

• =

average latency on the underlying topology

- Nodes close on ring, but far away in Internet
- Goal: put nodes in routing table that result in few hops and low latency

# Latency stretch in Chord

[Ratnasamy et al. 2001]

A Chord network with  $N(=8)$  nodes and  $m(=8)$ -bit key space

# Achieving Robustness

- To improve robustness each node maintains the  $k$  ( $> 1$ ) immediate successors instead of only one successor
- In the `notify()` message, node A can send its  $k-1$  successors to its predecessor B
- Upon receiving `notify()` message, B can update its successor list by concatenating the successor list received from A with A itself

- In a system with 1,000s of machines, some machines failing / recovering at all times
- This process is called *churn*
- Without repair, quality of overlay network degrades over time
- A significant problem deployed DHTs systems

*Observation: in >50 % cases, MTBF in order of minutes..*

# Multiple solutions...

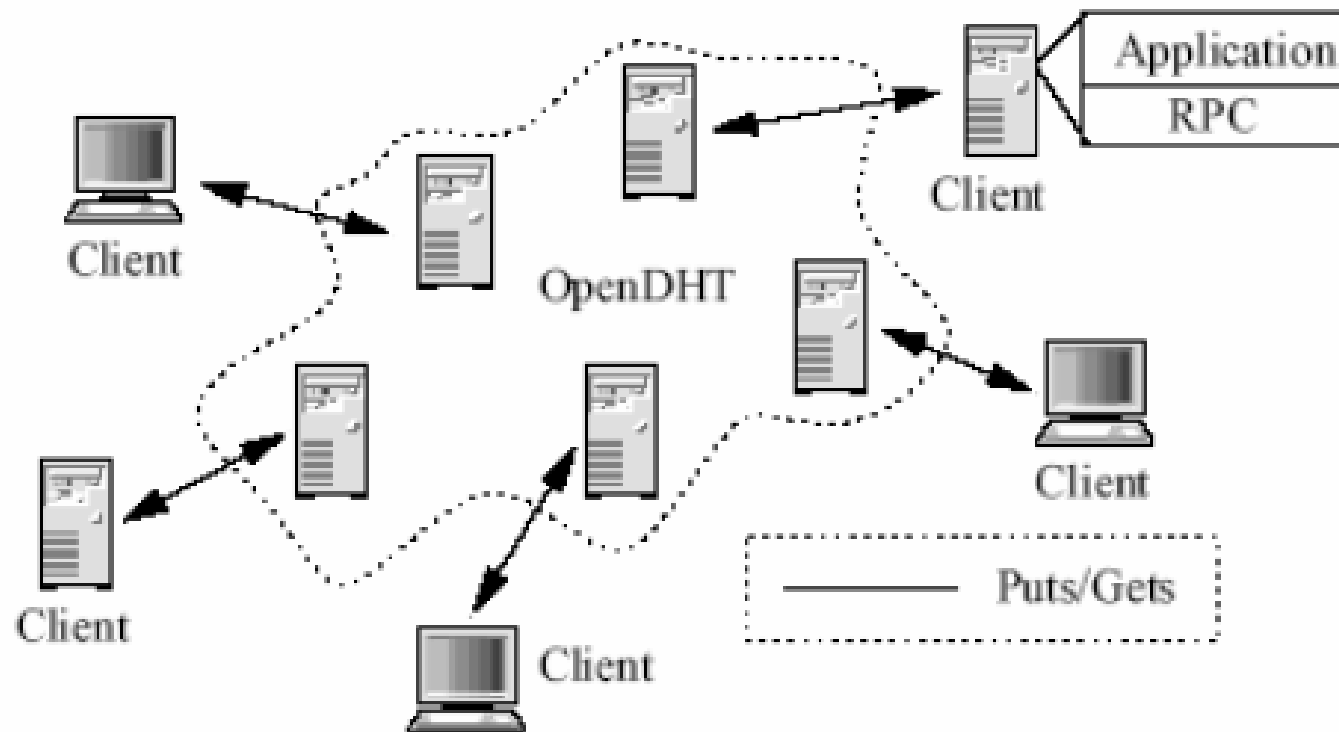

- Chord
- Tapestry
- Pastry
- CAN
- ....

- File sharing [CFS, OceanStore, PAST, ...]
- Web cache [Squirrel, ...]
- Censor-resistant stores [Eternity, FreeNet, ...]
- Application-layer multicast [Narada, ...]
- Event notification [Scribe]
- Naming systems [ChordDNS, INS, ...]
- Query and indexing [Kademlia, ...]
- Communication primitives [I3, ...]
- Backup store [HiveNet]
- Web archive [Herodotus]

- A single DHT (namely, Open DHT) is shared across multiple applications, thus amortizing the cost of deployment.
- Applications inherit some security and robustness from DHT
  - DHT replicates data
  - Resistant to malicious participants
- Low-cost deployment
  - Self-organizing across administrative domains
  - Allows to be shared among applications

- DHT as an Infrastructure

**Open DHT Architecture**

# Open DHT Deployment Model

- A single DHT (namely, Open DHT) is shared across multiple applications, thus amortizing the cost of deployment.
- Each DHT node serves as a **gateway** into the DHT for clients.
- Any Internet-connected computer can act as client:
  - Clients of Open DHT do not need to run a DHT node
  - using DHT services, i.e. can store or *put* key-value pairs in Open DHT, and can retrieve or *get* the value stored under a particular key
- Each DHT node serves as a **gateway** into the DHT for clients.
- An Open DHT client communicates with the DHT through the gateway of its choice using an RPC over TCP. **The gateway** processes the operations on client's behalf.
- Because of this, the service is easy to access from virtually every programming language

# Naming – summary...

- We have discussed the Duality:
  - Name (object id) vs: address
  - Naming: finding the address out of the name...
  - **Solutions?**
- We have already discussed DNS
  - Structuring of the name SPACE necessary!
- We have just discussed DHTs:
  - A solution for a FLAT NAME SPACE!
- Are there any other options possible?

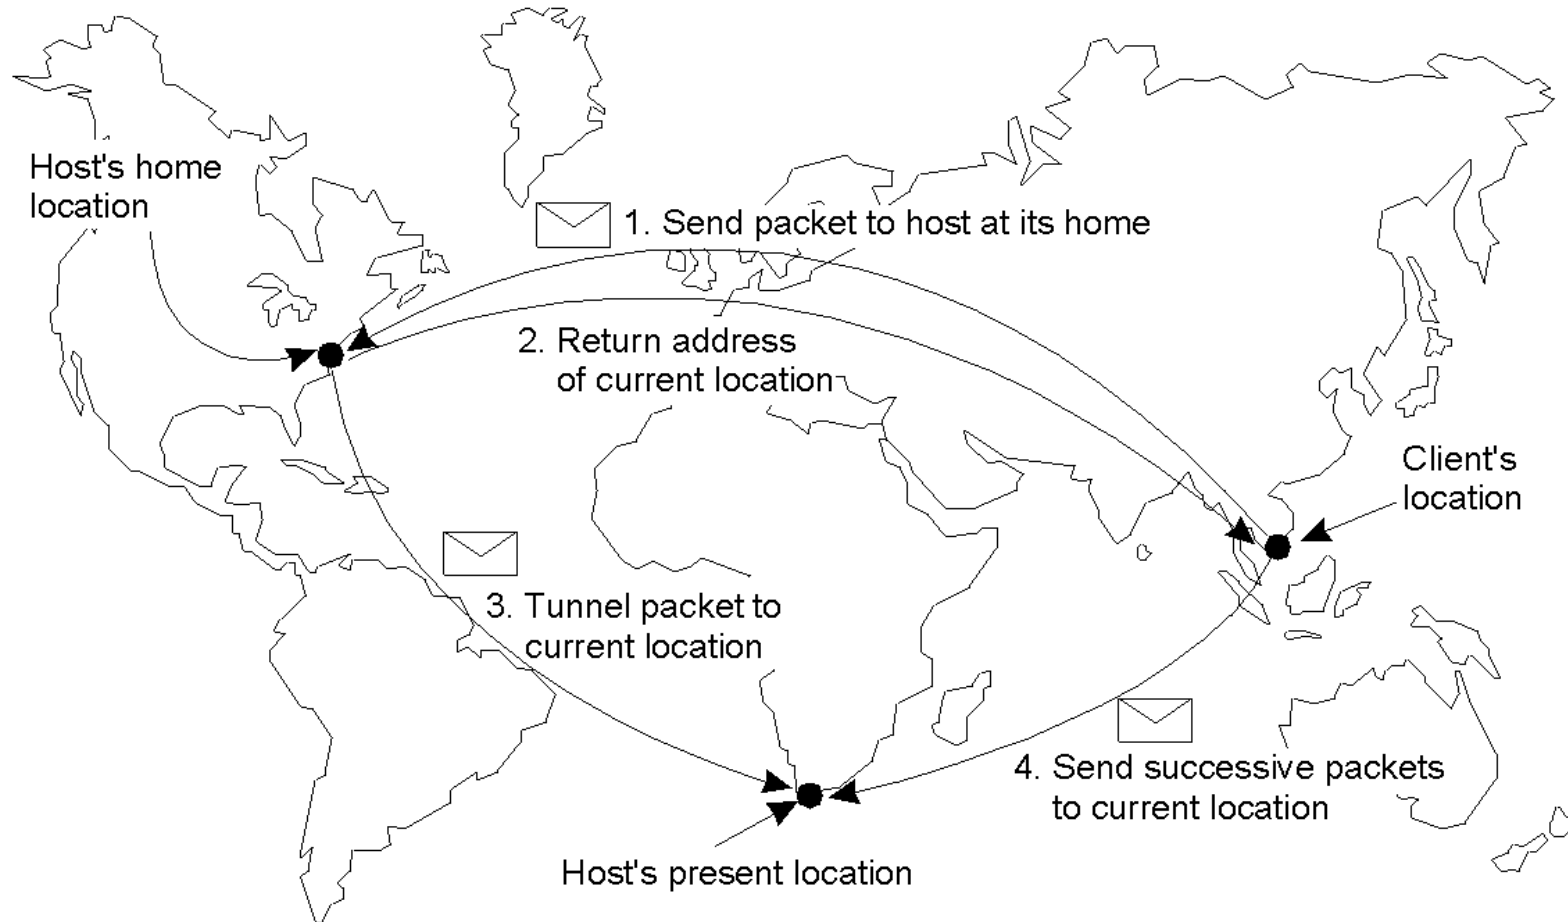

## Using a broadcast...

- To “owner of the name XXX”  
“please post me your address”
- Works only for RELATIVELY SMALL CONFIGURATIONS!
- Has “side effects”
  - What if the owner/administrator of the name XXX disappears ?
  - A third party can pretend to have the Name XXX  
(delegation of the responsibility!)
- *Look ahead: compare the ARP Service later....*

# Using the „Home Address“

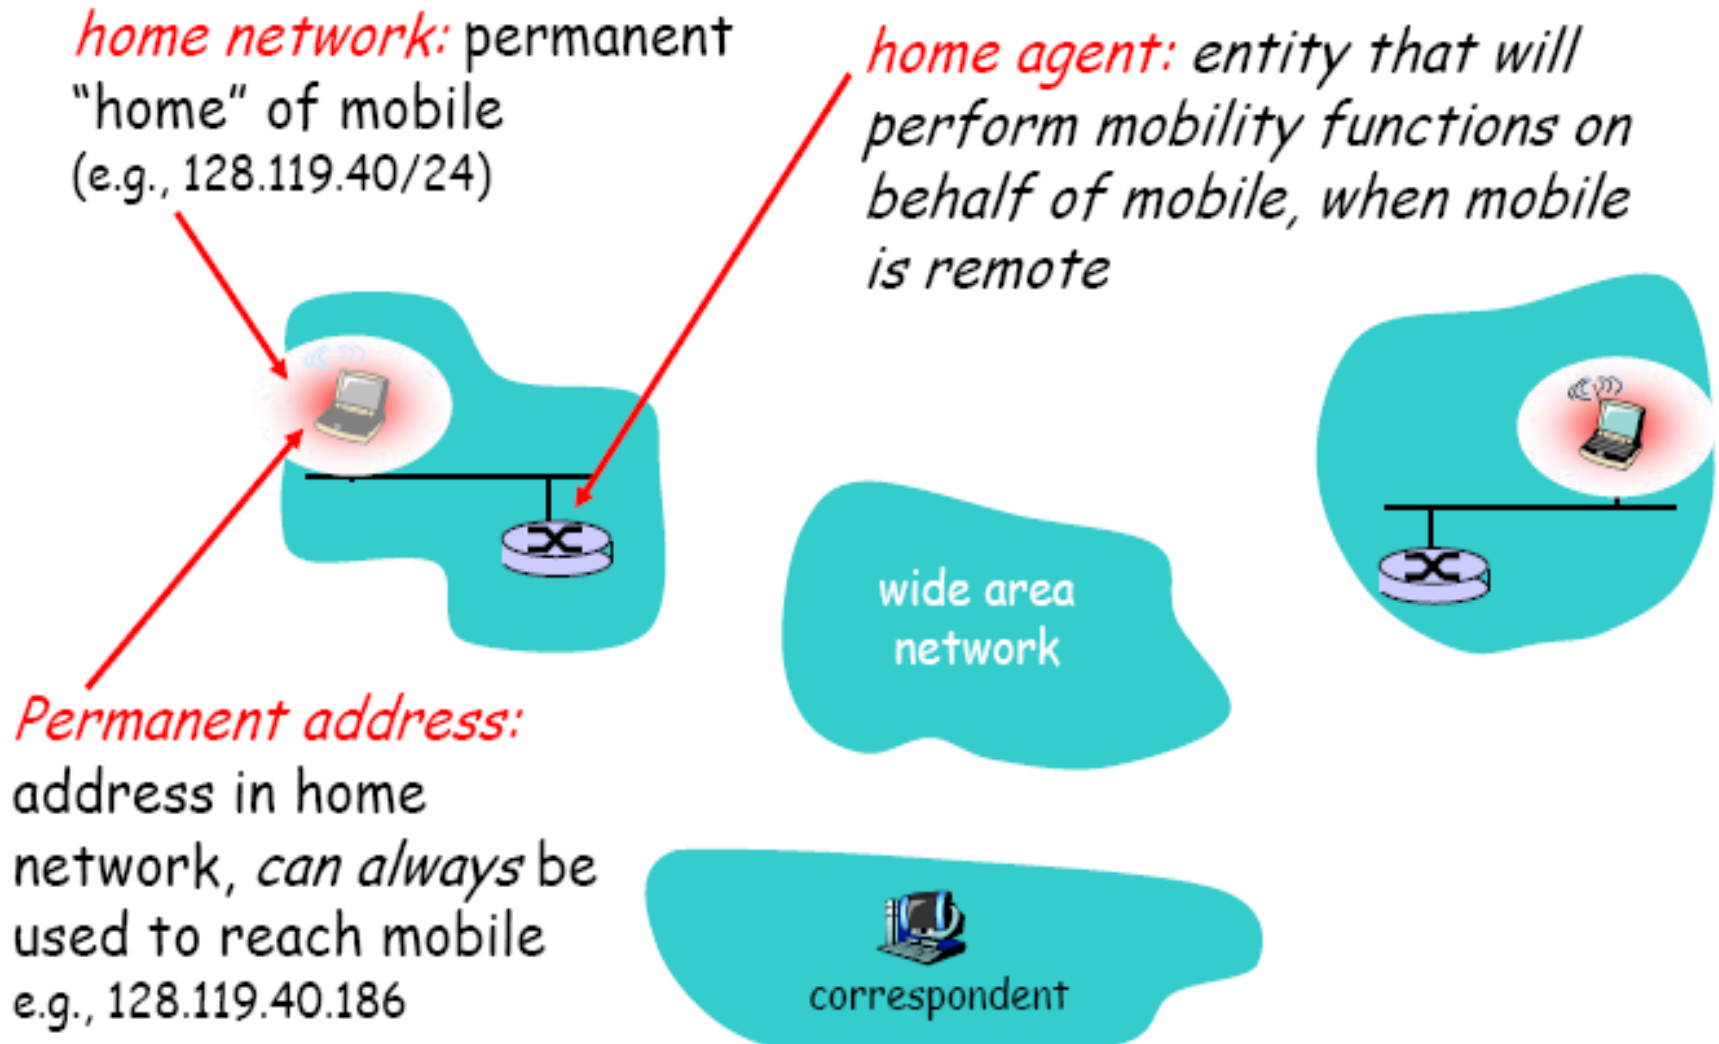

- The Name XXX is binded to a „home Address“
- Under the Home address a HOME REGISTER is maintained
  - a Data structure representing the the ACTUAL ADDRESS
- Resolving the actual address..
  - The “corresponding entity” uses the Home Address
  - Forwarding vs. answering with the “actual address”
- In both cases multiple Intermediate steps are possible
- Look ahead: Mobility support

# Home-Based Approaches

Disclosing the current address....

# Forwarding (see: cellular telephony)

# Mobility support

*Permanent address:* remains constant (e.g., 128.119.40.186)

*visited network:* network in which mobile currently resides (e.g., 79.129.13/24)

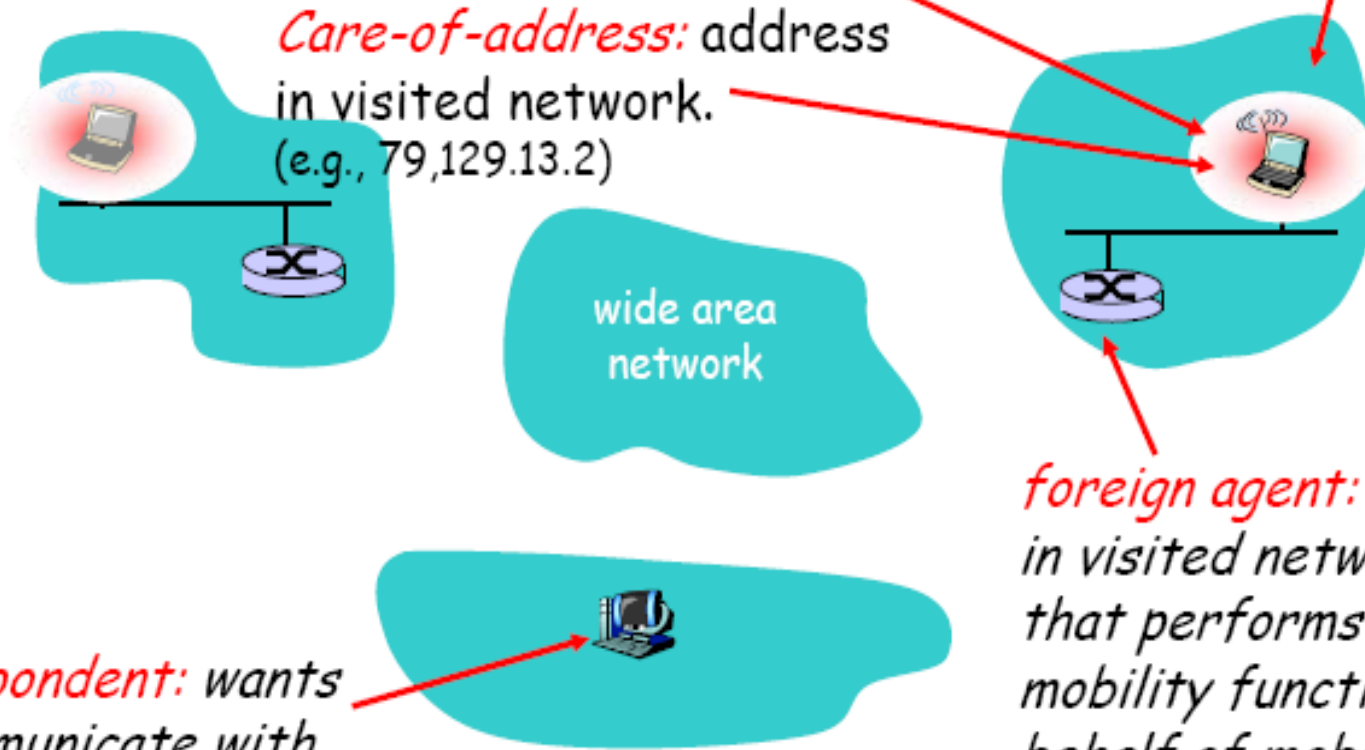

*Care-of-address:* address in visited network. (e.g., 79.129.13.2)

wide area network

*correspondent:* wants to communicate with mobile

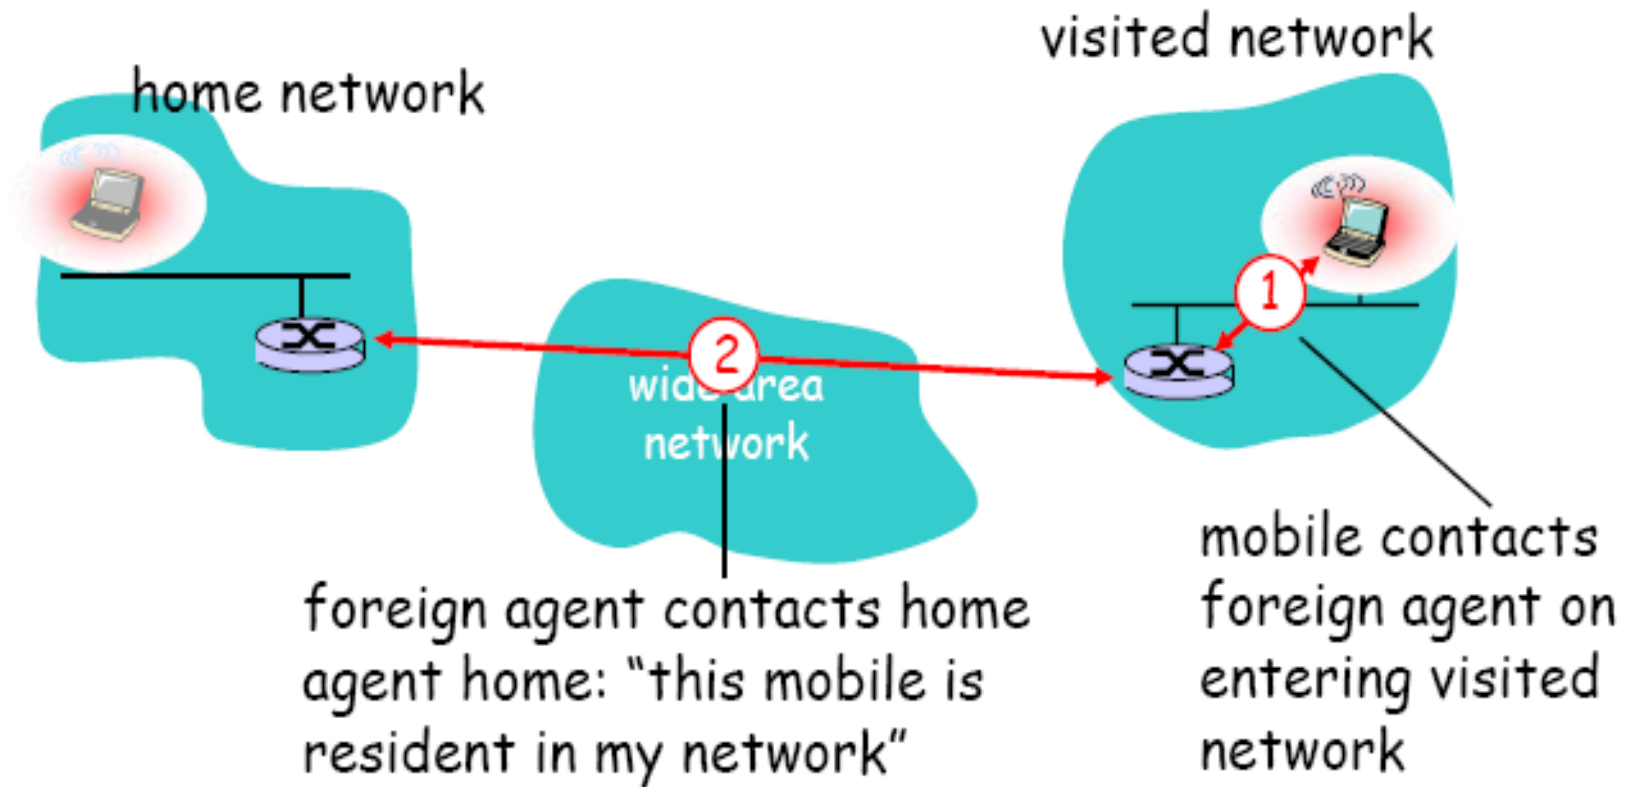

*foreign agent:* entity in visited network that performs mobility functions on behalf of mobile.

4c: Network Layer 13

# Updates

End result:

- ❑ Foreign agent knows about mobile
- ❑ Home agent knows location of mobile

# Indirect Routing
